Introduction

This report presents projections of population from 2025 to 2035 by age and sex for Illinois, Chicago, and Illinois counties produced for the Certificate of Need (CON) Program.

As actual future population trends are unknown, the projected numbers should not be considered a precise prediction of the future population; rather, these projections, calculated under a specific set of assumptions, indicate the levels of population that would result if our assumptions about each population component (births, deaths, and net migration) hold true. The assumptions used in this report, and the details presented below, generally assume a continuation of current trends.

Methodology

These projections for Illinois, Chicago, and Illinois counties were produced using a demographic cohort-component projection model. State total projections were produced using a linear regression model and the age and sex projections were produced using a cohort component method. County projected population by age and sex were controlled to state projected totals by sex. In the cohort component model, each component of population changes – birth, death, and net migration – is projected separately for each five-year birth cohort and sex. The cohort – component method employs the following basic demographic balancing equation:

$$P_1 = P_0 + B - D + NM$$

Where:

P_1 = Population at the end of the period.

P_0 = Population at the beginning of the period. B =

Resident births during the period.

D = Resident deaths during the period.

NM = Net migration (Inmigration – Outmigration) during the period.

The model roughly works as follows: for every five-year projection period, the base population, disaggregated by five-year age groups and sex, is “survived” to the next five-year period by applying the appropriate survival rates for each age and sex group; next, net migrants by age and sex are added to the survived population. The population under 5 years of age is generated by applying age specific birth rates to the survived females in childbearing age (15 to 49 years).

Base Population

These projections began with the July 1, 2020 population estimates by age and sex produced by the U.S. Census Bureau. The most recent census population of April 1, 2020 was the base for July 1, 2020 population estimates.

Special Populations

In 19 counties, the college dormitory population or adult inmates in correctional facilities accounted for 5% or more of the total population of the county; these counties were considered as special counties. There were six college dorm counties (Champaign, Coles, DeKalb, Jackson, McDonough, and McLean) and 13 correctional facilities counties (Bond, Brown, Crawford, Fayette, Fulton, Jefferson, Johnson, Lawrence, Lee, Logan, Montgomery, Perry, and Randolph) that qualified as special counties. When projecting the population, these special populations were first subtracted from the base populations for each special county; then they were added back to the projected population to produce the total population projections by age and sex. In the absence of 2020 census special population by age and sex, the base special population by age and sex from the 2010 population census was used for this purpose with the assumption that this population will remain the same throughout each projection period.

Mortality

Future deaths were projected by applying age and sex specific survival rates to each age and sex specific base population. The assumptions on survival rates were developed on the basis of trends of mortality rates in the individual life tables constructed for each level of geography for 2014-2016 and 2017-2019. Mortality for 2020 was considered abnormal because of COVID-19 and it will have no effect on mortality assumption for future years. The application of five-year survival rates provides a projection of the number of persons from the initial population expected to be alive in five years. The average of the 2014-2016 and 2017-2019 survival ratios was used for the 2025 mortality assumption, and the 2017-2019 survival ratios were used for the 2030 and 2035 mortality assumptions. Resident deaths data by age and sex from 2016 to 2019 were provided by the Division of Health Data and Policy (HDP), Illinois Department of Public Health.

Fertility

Total fertility rates (TFRs) were first computed for each county. For most counties, the projected 2025 TFRs were computed as the average of the 2015 and 2020 TFRs. The average of the 2015 and 2020 fertility rates were used for the 2025 assumption, and the 2020 fertility rates were used for the 2030 and 2035 assumptions. The age-specific birth rates (ASBR) were next computed for each county by multiplying the 2020 ASBR by each projected TFR. Total births were then projected for each county by applying age-specific birth rates to the projected female population of reproductive ages (15 to 49 years). The total births were broken down by sex, using an assumed sex-ratio at birth. These births were survived by five years applying assumed survival ratios to get the projected population for the age group 0-4. For the special counties, special populations by age and sex were taken out before computing age-specific birth rates. The resident birth data used to compute age-specific birth rates for 2015 and 2020 came from HDP. Births to females younger than 15 years of age were added to those of the 15-19 age group and births to women older than 49 years of age were added to the 45-49 age group.

Net Migration

Migration is the major component of population change in Illinois, Chicago, and Illinois counties. The state is experiencing a significant loss of population through internal (domestic migration within the U.S.) net migration. Unlike data on births and deaths, migration data based on administrative records are not available on a regular basis. Most data on migration are collected through surveys or indirectly from administrative records (IRS individual tax returns). For this report, net migration trends have been reviewed using data from different sources and methods (such as residual method) from the University of Wisconsin, Madison; Illinois Department of Public Health; individual exemptions data from the Internal Revenue Service; and survey data from the U.S. Census Bureau. Based on knowledge gained through this review and of levels of net migration from different sources, assumptions have been made that Illinois will have annual net migrants of -40,000, -30,000, and -30,000 during 2020-2025, 2025-2030, and 2030-2035, respectively. These figures have been distributed among the counties, using age and sex distribution of net migrants during 1995-2000. The 2000 population census was the last decennial census, which included the question "Where did you live five years ago?" The age and sex distribution of the net migrants was derived using answers to this question. The net migration for Chicago has been derived independently, using census survival method for 1990-2000 and 2000-2010 under the assumption that the annual net migration for Chicago will be -20,000, -15,000, and -12,000 for 2020-2025, 2025-2030, and 2030-2035, respectively. The age and sex distribution from the 2000-2010 net migration was used to distribute the net migrants for the projection periods.

Conclusion

These projections were prepared for use by the Certificate of Need (CON) Program of the Illinois Health Facilities and Services Review Board and are produced using evidence-based techniques, reasonable assumptions, and the best available input data. Effects of any unusual events, such as tornados or influx of asylum seekers, were not included in the development of assumptions for these population projections. Some adjustments were made by sex for Jasper and Pope counties because of small number problems. Other potential users of these projections are state agencies, the Board of Higher Education, local health departments, and academic institutions. As assumptions of future demographic trends may contain errors, the resulting projections are unlikely to be free of errors. In general, projections of small areas are less reliable than those for larger areas, and the farther in the future projections are made, the less reliable they may become. When possible, these projections should be regularly reviewed and updated, using more recent birth, death, and migration data.
